Hypothesis and Objectives

Hypothesis

Oral administration of resveratrol at a dose of 2 grams per day for 3 months will lead to enhanced exercise endurance as well as physiologic and molecular correlates demonstrating changes in signal transduction, gene expression, and other markers of improved oxidative capacity and muscle function.

Objectives

Primary Objective

To determine if oral resveratrol administered for 3 months will improve exercise endurance and physiologic functions by measurement of peak VO$_2$ and submaximal aerobic capacity as compared to a placebo control group.
Secondary Objectives

To determine if administration of resveratrol induces molecular alterations of metabolic pathways important for improved muscle cell energetics, lipid metabolism, insulin sensitivity/glucose control, etc.

- For each experiment, comparisons will be made on tissue obtained from each patient prior to beginning resveratrol and at the end of the study, and between the resveratrol- treated and placebo groups.

To determine if resveratrol alters gene expression signatures of molecular pathways in muscle that regulate mitochondrial biogenesis, TCA cycle and ETC function, and fatty acid oxidation.

To determine if resveratrol improves oxidative phosphorylation in muscle as assayed by MR spectroscopy during exercise and the post-exercise recovery period.

To evaluate changes in levels of circulating inflammatory cytokines, growth factors, and hormones, to include (but not limited to) TNF-\(\alpha\), IL-6, IGF-1, and adiponectin.

To determine if resveratrol increases mitochondria content in muscle by performing quantitative PCR of mitochondrial DNA in biopsy samples.

To evaluate alterations in systemic lipid metabolism by measuring fasting levels of serum cholesterol, LDL, HDL, triglycerides.

To determine effects of RSV on fasting glucose levels, insulin resistance, and glucose challenge.
Pathways and Genes of Interest

- PGC-1α and PGC-1β, SIRT1 (Civitarese et al, 2007), activators and downstream pathways (i.e. eNOS)

- AMPK downstream targets: Nampt (Fulco et al., 2008), Akt/mTOR inhibition

- Mitochondrial biogenesis: Nrf-1, Nrf-2, ERRα, TFAM (Lagouge et al., 2006)

- TCA: citrate synthase (Civitarese et al., 2007)

- ETC: cytochrome c oxidase II (COX II) (Civitarese et al., 2007), Ucp3 (Barger et al., 2008), cytochrome c (Lagouge et al., 2006)

- FA metabolism: PPARα/δ, β-hydroxyacyl-CoA dehydrogenase (Civitarese et al., 2007), Pdk4, CPT1 (Barger et al., 2008), adiponectin receptors1, 2 (Feige et al., 2008), MCAD (Lagouge et al., 2006)

- Fiber type: myoglobin, troponin 1 (Lagouge et al., 2006)
Stored Samples for Possible Future Analyses

RNA will be isolated from peripheral blood leukocytes for analysis of peripheral blood lymphocytes isolated pre- and post-resveratrol.

- Although lymphocytes are not thought to be a primary target of resveratrol’s metabolic effects, they are accessible in all patients and may provide a signal of PD activity of this drug.

Muscle tissue obtained pre- and post-resveratrol (or placebo) will be stored for:

- Histologic and immunohistochemical analysis for mitochondrial content and structure, muscle fiber type, fat deposition

- Protein lysates for assays of AMPK and PGC-1α levels and post-translational modifications, as well as modifications of downstream targets (pAMPK, pACC, acetylated-PGC-1α)
Subject Selection and Eligibility

Inclusion criteria

- Age $\geq$ 60-75
- BMI 30-35 kg/m$^2$
- Normal laboratory tests of organ function:
- Ability to perform peak VO$_2$ and submaximal aerobic exercise tests.

Exclusion criteria

- No history of myopathy or known disease of muscle.
- No chronic steroid use
- No history of coronary artery disease, stroke, HIV, hepatitis B or C, active peripheral vascular disease
- No contraindication to performing peak VO$_2$ or submaximal aerobic exercise tests including a history of coronary artery disease, severe COPD, significant hip or knee arthritis, etc.
- Contraindication to vastus lateralis muscle biopsy is not an exclusion criteria (need 10 biopsies/group).
- Patients are eligible even if they have contraindications to MR spectroscopy.
- Individuals who exercise regularly ($\geq$30 minutes more than once a week, including vigorous walking) are excluded. During the course of the study, participants should not alter their sedentary life style.
Study Design

Double blind, randomized study
Resveratrol (RevGenetics, IND) 2g/d versus equal number of placebo capsules for 12 weeks
20 subjects will be enrolled into each arm
10 patients in each arm will receive muscle biopsies prior to beginning and after 12 weeks of RSV.

Pre-treatment evaluation:
Eligibility and randomization
- Peak VO₂
- SubMax exercise
- Muscle biopsy (GEP)
- Blood: leukocytes, cytokines, lipids
- MR spectroscopy
- OGTT

Day 1:
Begin treatment

Day 14:
Evaluate for AE, tolerability

Day 29:
2nd peak VO₂
2nd SubMax exercise
Blood: leukocytes, cytokines, lipids

Day 57 (8 weeks):
3rd peak VO₂
3rd SubMax exercise
Blood: leukocytes, cytokines, lipids

Day 85 (12th week):
4th peak VO₂
4th SubMax exercise
2nd muscle biopsy
Blood: leukocytes, cytokines, lipids
2nd MR spectroscopy
2nd OGTT

Each visit will include: history (evaluation of AE), physical exam, routine labs (CBC, comprehensive metabolic panel, pill counts)
Statistical Considerations

The main objective of the study is to assess whether orally administered resveratrol can induce specific physiologic and/or molecular alterations to improve muscle function of elderly patients. Eligible patients will be randomized into two groups, treated with resveratrol or placebo.

The corresponding end-points will be change in peak VO₂ and the submaximal exercise capacity. Measurements will be taken for each study participant at baseline, i.e., prior to resveratrol, at 4, 8 weeks, and at the completion of the study at 12 weeks.

The time-averaged difference in peak VO₂ between the two groups will be estimated. A power analysis is based on a meaningful difference ($d$) between the average response for two groups to be detected. According to Diggle et al. (1996), the appropriate statistical model is

$$(\text{Peak VO}_2)_{ij} = \beta_0 + \beta_1 x + \epsilon_{ij}, j = 1, \ldots, n; i = 1, \ldots, 2m,$$

where $x$ is the group/treatment indicator variable. With type I error $\alpha = 0.05$, $n=4$ repeated measurements, and $m=20$ subjects per group, the table below gives the smallest difference that can be detected with an adequate power of at least 0.80 for several plausible values of correlation ($\rho$). The values for meaningful differences in time-average peak VO₂ and correlation between repeated observations $\text{Corr}(Y_{ij}, Y_{ik}) = \rho$ for all $j \neq k$, are chosen based on our preliminary data.

Important Questions for the Clinical Trial

Does RSV have biological activity in humans?

- Insulin/glucose homeostasis
- Fat metabolism
- Mitochondrial biogenesis and energetics
- Muscle efficiency (strength, endurance)
- Sarcopenia and frailty

What is the PK/PD relationship?

- Do RSV metabolites have biologic activity?
- Is the low PK profile of the parent compound sufficient to activate the PGC-1α program in muscle?

What is the optimal biologic dose, schedule, and duration of treatment?

Does RSV activate both AMPK and SIRT1 in vivo and is this necessary for beneficial effects on mitochondria and muscle?

NOTE: Values are the mean of n = 10 with coefficient of variation (in percent) or range in brackets.

Abbreviations: AUC<sub>inf</sub>, area under the concentration versus time curve to time infinity; C<sub>max</sub>, maximal plasma concentration; T<sub>max</sub>, median time of maximal plasma concentration; C<sub>av</sub>, average plasma concentration; CL/F, apparent total body clearance (calculated as dose/AUC<sub>inf</sub>); CL<sub>R</sub>, apparent renal clearance approximated by amount excreted with urine within 24 h over AUC<sub>0-24</sub>; V/F, apparent volume of distribution.

*<sup>n</sup> = 1, value for AUC<sub>inf</sub> at the lowest dose could be established in only one participant.

RSV Improves Mitochondrial Function and Protects against Metabolic Syndrome by Activating SIRT1 and PGC-1α

1. Treatment of mice with RSV (15 weeks, serum levels 10-120 ng/ml) increased aerobic capacity (running time, $O_2$ consumption in muscle fibers)
2. RSV was associated with induction of genes for OxPhos, mitochondrial biogenesis, conversion to oxidative type I muscle fibers, and cold tolerance (BAT) that were associated with PGC-1α deacetylation (by SIRT1).
3. RSV treatment protected mice against diet-induced obesity and insulin resistance.

Low dose RSV partially mimics CR and retards aging parameters in mice.

SIRT1 levels and PGC-1α transcriptional activity in response to CR and resveratrol (4.9 mg/kg/d, 14-30 mo).

Conclude: low doses of RSV fail to activate PGC-1α pathway.

Unclear which way levels of SIRT1 should go (elderly, they are purported to decrease). SIRT1 activity is regulated allosterically, not necessarily by protein levels.
